1. Dashboard Overview

The Tableau dashboard developed for this project was created to analyze food ordering behaviour and consumer trends using interactive visualizations. It brings together customer, revenue, delivery, and cuisine data from a single online food ordering dataset into one connected view, allowing stakeholders to explore patterns that would otherwise remain hidden in raw spreadsheet data.

Rather than presenting static numbers, the dashboard is built around interactivity — filters, parameters, and linked charts let a viewer drill into any city, cuisine, meal type, or customer segment and immediately see how the rest of the visualizations respond. This makes the dashboard useful both as a reporting tool for management and as an exploration tool for analysts looking to answer new questions as they come up.

The dashboard provides insight into the following areas:

- Customer Behaviour — how different age groups and company types order food
- Revenue — how order value is distributed across cities, cuisines, and meal types
- Delivery Performance — how delivery time is distributed across all orders
- Cuisine Analysis — which cuisines are most and least preferred by customers
- City Analysis — how order volume and value compare across cities

The key objectives behind building this dashboard were to:

- Analyze customer ordering behaviour across age groups and company types
- Compare city-wise performance in terms of order volume and order value
- Evaluate revenue contribution across cuisines and meal types
- Improve business decisions through data-driven, interactive insights rather than static reporting

Together, these objectives shape a dashboard that is not just descriptive but genuinely decision-oriented — every chart on the dashboard maps back to a specific business question the stakeholders care about.

2. Interactive Dashboard

Figure 1. Interactive Tableau Dashboard

The dashboard combines KPI cards, a heat map, bar charts, a pie chart, and interactive filters to provide a complete, at-a-glance view of business performance. KPI cards summarize the platform's overall totals; the heat map compares cuisine performance across cities; bar charts break down orders by age group, restaurant type, and company type; the pie chart shows the overall cuisine preference split; and the filters and parameters let the viewer narrow the entire view down to a specific city, cuisine, or meal type of interest.

3. Dashboard Features

Feature	Purpose
KPI Cards	Business Summary
Heat Map	City vs Cuisine Analysis
Bar Charts	Order Comparison
Pie Chart	Cuisine Distribution
Filters	Interactive Analysis
Parameter	City Selection

Together, these features allow users to perform interactive business analysis rather than simply reading a static report. A viewer can start from the KPI cards for a high-level summary, use the heat map and bar charts to spot patterns across cities and cuisines, apply filters and parameters to focus on a specific segment, and use the pie chart to understand overall distribution — all within a single connected view.

4. Tableau Story

Figure 2. Tableau Story

The Tableau Story presents the dashboard's insights in a logical sequence, guiding the viewer through the project's key findings one step at a time. Rather than presenting every chart at once, the story walks through customer behaviour, revenue, and delivery performance in order, helping stakeholders understand the business findings step by step and building toward a clear, well-supported conclusion.

5. Tableau Public

Tableau Public Link

[\(Link Here\)](#)

Tableau Public allows stakeholders to access the dashboard online without installing Tableau Desktop. Anyone with the link can open the dashboard directly in a web browser, interact with its filters and parameters, and explore the data for themselves — making it a convenient way to share the project with reviewers, recruiters, or business stakeholders who may not have Tableau installed.

6. GitHub Repository

GitHub Repository Link

[\(Link Here\)](#)

The repository contains the full project documentation, dashboard screenshots, the Tableau workbook, written reports, and the underlying dataset, all organized according to the project phases — from initial data preparation and cleaning through to dashboard development and final reporting. This structure makes it straightforward for anyone reviewing the project to follow the work from raw data to finished dashboard.

7. Conclusion

This project demonstrates how a Tableau dashboard can successfully transform raw food ordering data into meaningful business insights through interactive visualizations. By bringing together customer, revenue, delivery, and cuisine information into a single connected view, the dashboard makes it possible to move beyond static reporting and into genuine, exploratory business analysis.

The dashboard supports business decision-making at multiple levels: it helps stakeholders understand customer behaviour across age groups and company types, identify operational improvements in delivery performance, and evaluate revenue contribution across cities, cuisines, and meal types. Because every chart is interactive and connected through filters and parameters, users are not limited to the questions the dashboard's creator anticipated — they can explore the data on their own terms and arrive at insights specific to their own business needs.

Taken together, the KPI cards, heat map, bar charts, pie chart, and Tableau Story combine to tell a complete, coherent story about food ordering behaviour and consumer trends. This project reflects not only the technical work of building a dashboard in Tableau, but also the broader discipline of Business Intelligence: taking raw, disconnected data and turning it into a clear, actionable, and genuinely useful decision-making tool.
